Introduction

Cardiovascular diseases (CVDs) are the most common causes of death worldwide, accounting for approximately 17.9 million deaths each year. Heart failure is a common consequence of cardiovascular diseases (CVDs), including coronary heart disease, cerebrovascular disease, rheumatic heart disease, congenital heart disease, and cardiomyopathy. Cardiovascular disease is a term that encompasses a variety of illnesses affecting the heart and blood vessels, including coronary heart disease, cerebrovascular disease, rheumatic heart disease, congenital heart disease, and cardiomyopathy. Cardiovascular disease is a major cause of death and disability worldwide, with a significant impact on public health and healthcare systems. The prevalence of cardiovascular disease is increasing in many countries, mainly due to the aging population, lifestyle changes, and the rise in risk factors such as obesity and diabetes.

Data Frame Description

Data Frame Description

The data frame contains information about various cardiovascular diseases (CVD) and their associated risk factors. The data frame includes variables such as age, gender, blood pressure, cholesterol levels, smoking status, alcohol consumption, physical activity, and other relevant factors that may contribute to the development of cardiovascular diseases. The data frame may also include information on the presence or absence of cardiovascular diseases, such as coronary heart disease, cerebrovascular disease, rheumatic heart disease, congenital heart disease, and cardiomyopathy. The data frame may be used to study the prevalence and risk factors associated with cardiovascular diseases in different populations and to develop predictive models for the diagnosis and prevention of cardiovascular diseases.
